

ABSTRACT OF THE DISCLOSURE

1

2 An intelligent flash system for a digital camera having
3 components including an image optical pickup, an interface
4 circuit, a flash unit and a processor. Upon activation of the
5 camera, ambient lighting conditions are evaluated and if flash
6 energy is required, a first low energy pre-flash is radiated,
7 the reflected light received by the optical pickup having a
8 multiplicity of pixels, and the output of the pixels converted
9 to image intensity data by the interface circuit. The processor
10 samples the image intensity data, weighing the center image area
11 more heavily, and creates a histogram plot of quantity of pixels
12 v.s. intensity, and separates the plot into a bar graph from
13 which a determination of exposure is obtained. The histogram is
14 then used to calculate a multiplicative scaling factor used to
15 multiply the first flash energy to an estimate of a flash energy
16 for correct exposure. Conditions of extreme over and under
17 exposure result in the activation of a second flash at an
18 adjusted energy level. The image data of the second flash is
19 then analyzed and the exposure compared with the result of the
20 first flash. A final determination of flash energy is then made
21 based upon the results.
